Feldspars	26
Apatite	27

INTRODUCTION

This paper presents quantitative electron microprobe analyses of minerals in core samples from the Dry Valley Drilling Project (DVDP) holes 1 and 2. Preliminary petrographic descriptions of some of the samples and detailed core logs are given elsewhere (Treves and Kyle, 1973).

In the tables contained herein the analysed samples are listed in order of increasing depth within each hole. The sample number refers firstly to the hole and this is followed by the depth in metres. Analyses for all ferromagnesium minerals are listed in order of increasing FeO. Feldspars and apatites are listed by increasing Na₂O and CaO respectively. Where there is more than one analysis per grain the core is always listed first. To designate the position of analysis the following symbols are used:

- C - core
- R - rim
- I - intermediate between core and rim

Scans were made to determine the homogeneity of grains and where only one analysis is presented this usually indicates no zoning or only weak zoning. In such grains the analysis was made near the centre.

The following lower case symbols were used where applicable to denote the type of crystal analysed:

- a - alteration product
- g - groundmass; used only when the sample was porphyritic
- i - inclusion within another mineral
- x - xenocryst
- (010) - sector when crystal showed sector zoning.

Analytical Method

Analyses were made using a Japanese Electron Optics Laboratory electron probe X-ray microanalyser Model JXA-5A at the Department of Geology, University of Otago. Instrumental settings were: 15kV accelerating potential, 2.0 to 3.0 X10⁻⁸ amps specimen current on periclase and a 1-2 μm beam size. Corrections for absorption, fluorescence and atomic number were applied using the method of Bence and Albee (1968) and the alpha correction factors, for a 40° takeoff angle, listed in Kushiro and Nakamura (1970). Corrections for dead-time, background and drift were made. Each complete analysis and also the partial analyses of pyroxenes and olivines represents a minimum of 5 individual 10 second counts per element. For the feldspars it was usual only to accumulate a single 10 second count. Corrections for the partial analyses were made assuming the mineral was stoichiometric and consisted purely of the end members CaSiO₃, MgSiO₃, FeSiO₃ for the pyroxenes, Fe₂SiO₄, Mg₂SiO₄ for the olivines and KAlSi₃O₈, NaAlSi₃O₈, CaAl₂Si₂O₈ for the feldspars. Data was reduced at the Computer Centre, University of Canterbury.

Standard materials were as follows: natural albite from Amelia (Na), adularia from Gotthard (K), hematite from Sennin Mine (Fe), maganosite from Nodatamagawa Mine (Mn); synthetic corundum (Al), wollastonite (Ca, Si), NiO(Ni), Cr₂O₃ (Cr), periclase (Mg), rutile (Ti).

In all analyses total iron was determined as FeO, in the pyroxenes however Fe₂O₃ was calculated by allotting equivalent amounts of Fe₂O₃ to Na₂O.

Recalculation of magnetite and ilmenite analyses were made using the methods of Carmichael (1967). For the spinels total Fe has been assigned to Fe²⁺ and Fe³⁺ on the assumption of a formula R₂²⁺ R₂³⁺O₄ with dissolved Fe₂TiO₄.

Acknowledgements

The author is indebted to Dr Yasuo Nakamura for instruction on the use of the electron microprobe and to Professor D. S. Coombs for allowing the use of the instrument at Otago University. Technical assistance was provided by Messrs E. McKenzie, K. Mason and J. Pillidge, all of Otago University, and Mrs G. S. Finnegan of the Computer Centre, University of Canterbury. To the staff and students of the Department of Geology, Otago University the author expresses his thanks for their kind hospitality. Dr P. J. Barrett, Director of the Antarctic Research Centre, Victoria University is thanked for his help in preparation of this report and Mrs M. A. Phillips for typing the tables. Financial support was provided by the Internal Research Committee of Victoria University grants no. 52/72 and 47/73.
